UPI TRANSACTIONS ANALYSIS DASHBOARD

Project Report & Business Recommendations

PROJECT OVERVIEW

An interactive Power BI report designed to explore UPI transaction patterns across time, payment methods, transaction types, banks, merchants, locations, customer demographics and remaining balances.

Project Title	UPI Transactions Analysis Dashboard
Primary Tool	Microsoft Power BI Desktop
Supporting Features	Power Query, data modelling, interactive visuals and report filters (where configured)
Input File	UPI Transactions.pbix report file supplied for review
Report Type	Dashboard documentation, interpretation framework and recommendations

Prepared as a structured project document for presentation, portfolio use and future dashboard improvement.

1. Project Overview

Unified Payments Interface (UPI) is widely used for quick digital payments. This project uses Power BI to organise transaction data into visual summaries so a user can explore how transaction amounts and balances vary over time and across payment characteristics.

Project objectives

• Understand transaction activity by transaction date and month.

• Compare transaction amount and remaining balance over time.

• Explore transaction distribution by payment method and transaction type.

• Review banks used to send and receive funds, merchant names and transaction purpose.

• Compare patterns by city, device type, gender and age group.

• Support evidence-based monitoring and identify areas for deeper investigation.

Tools and technologies

Tool / Feature	Role in the project
Power BI Desktop	Builds the report pages, charts, cards and interactive exploration experience.
Power Query	Can be used to inspect, clean and transform source data before analysis.
Data model	Connects the transaction table fields to report visuals and aggregations.
Visual analytics	Makes trends and category comparisons easier to interpret.
Filters / slicers	Where included, help narrow the view by date, city, bank or transaction category.

Scope note: This report is based on the fields visible in the supplied PBIX report definition. The underlying transaction values were not independently recalculated here; therefore, no unverified totals, percentages or top-performing categories are claimed.

2. Dashboard Fields & Analysis Areas

The report contains visuals referencing the following transaction fields. These fields allow the dashboard to answer descriptive questions about transaction behaviour.

Analysis area	Fields / measures visible in the report	Questions it can help answer
Transaction value	Amount	How does transaction value change across dates or categories?
Balance monitoring	RemainingBalance	How does the recorded remaining balance trend over time?
Time trend	TransactionDate (month hierarchy)	Are there monthly peaks, dips or seasonal patterns?
Bank comparison	BankNameSent, BankNameReceived	Which sending and receiving banks appear most often or carry higher value?
Payment behaviour	PaymentMethod, TransactionType, Purpose	Which payment options, transaction types and purposes are common?
Merchant & location	MerchantName, City	How does activity differ by merchant or city?
Customer & device	Gender, Age Groups, DeviceType	How is activity distributed across demographic and device categories?
Currency	Currency	Are multiple currencies present, and are amounts compared on a consistent basis?

Suggested reading order

1. Start with total transaction amount and any available transaction-count KPI. 2. Check monthly trends. 3. Compare payment method and transaction type. 4. Explore bank, merchant and city breakdowns. 5. Use demographic and device fields to investigate differences, while avoiding assumptions about individuals.

Important validation checks

Confirm that TransactionDate is a true date, Amount and RemainingBalance are numeric, currency values are not mixed without conversion, blank category values are handled, and visuals use suitable aggregation. If each row represents one transaction, a transaction count should use a unique transaction ID where available; otherwise, document the counting method.

3. Findings Framework & Recommendations

The PBIX fields show that the dashboard is structured for transaction, time, bank, merchant, location and customer-category analysis. The following are practical recommendations to validate against the actual visual results before making business decisions.

Priority	Recommendation	Why it helps / suggested action
High	Add clear KPI cards	Display transaction count, total amount, average transaction value and distinct active customers if the required fields exist.
High	Validate date and currency logic	Use a proper calendar table and consistent currency treatment so monthly comparisons are reliable.
High	Investigate unusual amounts	Create a review view for unusually high or low amounts and duplicate transaction records; do not label these as fraud without further evidence.
Medium	Compare sending and receiving banks	Show transaction count and amount by bank, with clear definitions for sender and receiver perspectives.
Medium	Improve merchant and city analysis	Add ranked views and drill-through details to locate areas with high activity or unusual changes.
Medium	Review payment method and device patterns	Compare usage share and trends to help prioritise usability and customer-support improvements.
Medium	Add time-period comparisons	Include month-over-month change and year-over-year change only when the date range supports a fair comparison.
Ongoing	Document data quality	Track missing values, duplicate IDs, invalid dates and inconsistent category labels during refreshes.

Potential future enhancements

- Add a date slicer and consistent drill-through navigation.
- Use dynamic titles that reflect selected filters.
- Add tooltips with transaction count, total amount and average value.
- Create a data dictionary explaining each field and its business meaning.
- Add a refresh date and a short note describing the dataset period and limitations.

4. Conclusion

The UPI Transactions Analysis Dashboard provides a foundation for exploring digital-payment activity in Power BI. By bringing amount, remaining balance, transaction date, payment method, transaction type, bank, merchant, city, device and demographic fields into one report, it can help users investigate patterns and ask more focused business questions.

The most important next step is to validate the actual figures and chart behaviour, then apply the recommendations that are supported by the data. Conclusions about fraud, customer preferences or performance should only be made after checking data quality, sample coverage and appropriate comparison periods.

THANK YOU!

Thank you for your time and consideration.

Project	UPI Transactions Analysis Dashboard
Tool Used	Microsoft Power BI Desktop
Closing Note	Questions, feedback and suggestions for improvement are welcome.
